Hi Brain,

Thanks for the feedback.

On topic #1, agreed. We'll prioritize Material Equipment and Vendor Open Items (both ~60% savings), and work on formalizing a repeatable decision framework: identifying the deterministic characteristics (X) — e.g., mature BAPI coverage, high volume, low custom-field dependency — that indicate an object is a strong candidate for the BAPI + parallelism approach (Y), so we can apply the same logic to future objects.

On topic #2, we already have a Plan B specifically for **EWM Inventory**, so there is no need to involve SAP on this one yet.

Our trace analysis shows that the real cost per record does **not** come from the load using t-code (/SCWM/ISU), but from custom logic firing on every goods movement generated by the Initial Stock Upload:

Cost driver	% of cost per record
Custom Z/Y BAdIs (JVA + MIGO + Validation + PSA + Oil)	40%
Syclo mobile framework (change pointers)	20%
CIF/APO sync + Central Finance	12%
FI consistency checks + FINSC_* lookups	10%
Oil & Gas + Regulatory (FERC)	8%
Material Ledger cost component split	5%
Classification + number range + RFC checks	5%

In other words, the BAPI vs. t-code question is secondary here — the real lever is **reducing what fires during the cutover window**, not replacing /SCWM/ISU. This is exactly the "disable BAdIs during migration" principle we flagged separately, just more granular for this object. (But I identified two APIs for this process, and we can use them in the future.)

Based on this breakdown, our realistic reduction plan takes EWM Inventory from **~24h down to ~6–14h**, depending on how many optimization layers we apply (e.g., disabling custom BAdIs, deferring change pointers, bypassing CIF/APO sync during load, skipping non-essential regulatory/FI checks for the initial load and reconciling post-cutover).

We already have a detailed breakdown of the specific steps and expected gain per layer — happy to share that document if you'd like to review it. Just confirming this is already covered and doesn't need SAP involvement at this stage.

Best regards,

Thiago

Subject: Re: Syniti Surge - Data Load Optimization

+others.

Hi Thiago,

My thoughts are as follows:

- (1) I would prioritize anything where the expected savings is north of 50%.
- (2) I would request that we think through a Plan B on anything south of 50% (e.g. EWM Inventory).

On topic #1, I would ideally prefer that we focus on a repeatable and standardized process along with identifying the characteristics that make it a suitable approach. If we can generate over 50% savings for Material Equipment, then it would be great if we can say “when you see X, then you can do Y and expect similar savings” where the X are deterministic characteristics and the Y are structured and repeatable steps.

On topic #2, if we can agree that the BAPI approach will only gain us 10% on EWM Inventory, then we need to identify another option that would gain us more than 10%. Let us know if you want us to get SAP involved on this task for their ideas.

Thanks!

Subject: Re: Syniti Surge - Data Load Optimization

Hi Brian, Hi John

Based on my analysis and meetings held with Rocky, we identified an opportunity to reduce the total cutover load window from ~186h to a range of 94h–131h (a 30% to 50% reduction), by selectively migrating objects from LSMW/T-code to BAPIs with parallelism and package-level commits.

As a next step, we need to align with you on the **prioritization among the 7 mapped objects**, since the sprint schedule (Phase 1, 2, and 3) depends on this decision. Summary of the objects and their estimated gain potential:

#	Object	Current (h)	Realistic gain	Projected (h)	Savings (h)	% Savings
6	Material Equipment	40	50–75%	10–20	20–30	60%
5	Open Production Order	60	20–40%	36–48	12–24	30%
7	Open PO Conversion	30	40–60%	12–18	12–18	50%
2	Open Purchase Orders	12	40–60%	5–7	5–7	50%
3	Vendor Open Items	10	50–70%	3–5	5–7	60%
4	Maintenance Work Order	10	10–20%	8–9	1–2	15%
1	Inventory EWM	24	0–20%	20–24	0–4	10%
TOTAL		186		94–131	55–92	30–50%

Savings distribution by object (conservative scenario ~55h)

Our initial recommendation (quick wins) is to prioritize **Vendor Open Items, Open PO Conversion, Open Purchase Orders** and **Maintenance Work Order** (We did something similar in RI-775 and RI-871) for a technical POC, and leaving **Material Equipment, Open Production Order** and **Inventory EWM** for the next steps.

To move forward with sprint planning, we would like to confirm with you:

1. What order of priority would the team/business define among these objects?
2. Are there any deadline constraints or functional dependencies that should weigh more heavily than the estimated technical gain (e.g., objects critical for go-live)?

Ps. One recommendation that can already be applied now, and that will bring a significant gain in execution time, is disabling the BAdIs/user-exits for all these objects during the load window. According to the only trace log we have received so far, these BAdIs are currently active. Since this is a data migration (not day-to-day operational transactions), these business validations and enhancements are not required in this context and disabling them avoids redundant processing — reducing the overall execution time without impacting the integrity of the migrated data.

Best regards,
Thiago Battaglin

[@Danos, Anthony](#), [@Brumfield, John](#) - can we please get one contact per each account (LM, XOM) that can work with SAP and our product team on data load optimization, e.g. lmes from XOM and ???? from Lockheed?

Ideally, this should be someone technical, reliable, connected to the BASIS team, possessing at least a basic understanding of ABAP, and reasonably intelligent.

Today or tomorrow morning would be great....

Hello Raelene:

As Rocky mentioned in the meeting, we would like to 'running a trace using sample data to simulate loading scenarios similar to Exxon and other customers'. Could you please help us get the experts. We would like to schedule a quick meeting and collect the information.

Brahma
